Restless legs syndrome (RLS) is clinically defined by the presence of four clinical features: 1. an urge to move the limbs with or without sensations, 2. worsening at rest, 3. improvement with activity, 4. worsening in the evening or night. 1 Periodic limb movements of sleep (formerly called nocturnal myoclonus) 2 accompany RLS in most cases. 3 Wakeful movements, variable called dyskinesia while awake or periodic limb movements while awake, are also seen in RLS. Movements while awake, are also seen in RLS.
